Exceptions and file input/output

- try-raise-except-finally
- Exception
- control flow
- match case
- file open/read/write
- sys.stdin, sys.stdout, sys.stderr

Exceptions – Error handling and control flow

 Exceptions is a widespread technique to handle run-time errors / abnormal behaviour (e.g. in Python, Java, C++, JavaScript, C#)

- Exceptions can also be used as an advanced control flow mechanism (e.g. in Python, Java, JavaScript)
 - Problem: How to perform a "break" in a recursive function ?

Built-in exceptions (class hierarchy)

```
BaseException
 +-- SystemExit
 +-- KeyboardInterrupt
 +-- GeneratorExit
 +-- Exception
      +-- StopIteration
      +-- StopAsyncIteration
      +-- ArithmeticError
           +-- FloatingPointError
           +-- OverflowError
           +-- ZeroDivisionError
      +-- AssertionError
      +-- AttributeError
      +-- BufferError
      +-- EOFError
      +-- ImportError
           +-- ModuleNotFoundError
      +-- LookupError
           +-- IndexError
           +-- KeyError
      +-- MemoryError
      +-- NameError
           +-- UnboundLocalError
      +-- TypeError
      +-- ValueError
           +-- UnicodeError
                +-- UnicodeDecodeError
                +-- UnicodeEncodeError
                +-- UnicodeTranslateError
```

```
+-- OSError
     +-- BlockingIOError
     +-- ChildProcessError
     +-- ConnectionError
          +-- BrokenPipeError
          +-- ConnectionAbortedError
          +-- ConnectionRefusedError
          +-- ConnectionResetError
     +-- FileExistsError
     +-- FileNotFoundError
     +-- InterruptedError
     +-- IsADirectoryError
     +-- NotADirectoryError
     +-- PermissionError
     +-- ProcessLookupError
     +-- TimeoutError
+-- ReferenceError
+-- RuntimeError
     +-- NotImplementedError
     +-- RecursionError
+-- SyntaxError
     +-- IndentationError
          +-- TabError
+-- SystemError
+-- Warning
     +-- DeprecationWarning
     +-- PendingDeprecationWarning
     +-- RuntimeWarning
     +-- SyntaxWarning
     +-- UserWarning
     +-- FutureWarning
     +-- ImportWarning
     +-- UnicodeWarning
     +-- BytesWarning
     +-- ResourceWarning
```

Typical built-in exceptions

and unhandled behaviour

Python shell

```
> 7 / 0
  ZeroDivisionError: division by zero
> int('42x')
  ValueError: invalid literal for int() with base 10: '42x'
> x = v
  NameError: name 'y' is not defined
> L = [1] * 10 000 000 000
  MemoryError
> 2.5 ** 1000
OverflowError: (34, 'Result too large')
> t = (3, 4)
> t[0] = 7
  TypeError: 'tuple' object does not support item assignment
> t[3]
  IndexError: tuple index out of range
> t.x
AttributeError: 'tuple' object has no attribute 'x'
> x = \{\}
> x['foo']
| KeyError: 'foo'
> def f(x): f(x + 1)
> f(0)
RecursionError: maximum recursion depth exceeded
> def f(): x = x + 1
> f()
  UnboundLocalError: local variable 'x' referenced before assignment
```

Catching exceptions – Fractions (I)

```
fraction1.py
while True:
    numerator = int(input('Numerator = '))
    denominator = int(input('Denominator = '))
    result = numerator / denominator
    print(f'{numerator} / {denominator} = {result}')
Python shell
 Numerator = 10
 Denominator = 3
  10 / 3 = 3.33333333333333333
 Numerator = 20
 Denominator = 0
 ZeroDivisionError: division by zero
```

Catching exceptions – Fractions (II)

```
fraction2.py
while True:
    numerator = int(input('Numerator = '))
    denominator = int(input('Denominator = '))
    try:
        result = numerator / denominator
    except ZeroDivisionError:
        print('cannot divide by zero')
        continue
    print(f'{numerator} / {denominator} = {result}')
```

catch exception

Python shell

```
Numerator = 10
| Denominator = 0
| cannot divide by zero
| Numerator = 20
| Denominator = 3
| 20 / 3 = 6.66666666666667
| Numerator = 42x
| ValueError: invalid literal for int() with base 10: '42x'
```

Catching exceptions – Fractions (III)

```
fraction3.py
while True:
    try:
        numerator = int(input('Numerator = '))
        denominator = int(input('Denominator = '))
    except ValueError:
        print('input not a valid integer')
        continue
    try:
        result = numerator / denominator
    except ZeroDivisionError:
        print('cannot divide by zero')
        continue
    print(f'{numerator} / {denominator} = {result}')
```

Python shell

catch

exception

catch

exception

```
Numerator = 5
| Denominator = 2x
| input not a valid integer
| Numerator = 5
| Denominator = 2
| 5 / 2 = 2.5
```

fraction3.py while True: try: numerator = int(input('Numerator = ')) denominator = int(input('Denominator = ')) except ValueError: print('input not a valid integer') continue try: result = numerator / denominator print(f'{numerator} / {denominator} = {result}') except ZeroDivisionError: print('cannot divide by zero')

Python shell

```
Denominator = 1
```

OverflowError: integer division result too large for a float

exception not caught

Catching exceptions – Fractions (IV)

```
fraction4.py
while True:
    try:
        numerator = int(input('Numerator = '))
        denominator = int(input('Denominator = '))
        result = numerator / denominator
        print(f'{numerator} / {denominator} = {result}')
    except ValueError:
        print('input not a valid integer')
    except ZeroDivisionError:
        print('cannot divide by zero')
```

catch exceptions

Python shell

```
| Numerator = 3
| Denominator = 0
| cannot divide by zero
| Numerator = 3x
| input not a valid integer
| Numerator = 4
| Denominator = 2
| 4 / 2 = 2.0
```

Keyboard interrupt (Ctrl-c)

throws KeyboardInterrupt exception

```
infinite-loop1.py
print('starting infinite loop')
x = 0
while True:
   x = x + 1
print(f'done (\{x = \})')
input('type enter to exit')
Python shell
  starting infinite loop
  Traceback (most recent call last):
    File 'infinite-loop1.py', line 4, in <module>
      x = x + 1
  KeyboardInterrupt
```

```
infinite-loop2.py
print('starting infinite loop')
try:
   x = 0
   while True:
       x = x + 1
except KeyboardInterrupt:
   pass
print(f'done({x = })')
input('type enter to exit')
Python shell
  starting infinite loop
                       Ctrl-c
  done (x = 23890363)
  type enter to exit
```

Keyboard interrupt (Ctrl-c)

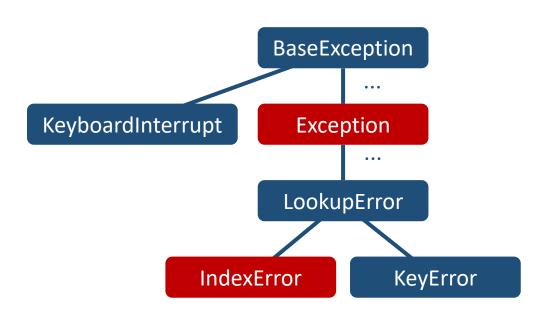

Be aware that you likely would like to leave the Ctrl-c generated
 KeyboardInterrupt exception unhandled, except when stated explicitly

```
read-int1.py
while True:
    try:
        x = int(input('An integer: '))
        break
    except ValueError: # only ValueError
        continue
print('The value is:', x)
Python shell
                            Ctrl-c
  An integer:
  KeyboardInterrupt
```

```
read-int2.py
while True:
    try:
        x = int(input('An integer: '))
        break
                                       catches
    except: # all exceptions
                                    KeyboardInterrupt
        continue
print('The value is:', x)
Python shell
  An integer:
                        Ctrl-c
  An integer:
                       Ctrl-c
  An integer:
```

(left) KeyboardInterrupt is unhandled (right) it is handled (intentionally?)

Exception class hierarchy

```
try:
    L[4]
except IndexError: # must be before Exception
    print('IndexError')
except Exception:
    print('Fall back exception handler')
```

```
try:
    L[4]
except Exception: # and subclasses of Exception
    print('Fall back exception handler')
except IndexError:
    print('IndexError') # unreachable
```

try statement syntax

```
try:
   code
except ExceptionType1:
   code # executed if raised exception instanceof
         # ExceptionType1 (or subclass of ExceptionType1)
except ExceptionType2:
   code # executed if exception type matches and none of
         # the previous except statements matched
else:
         # only executed if no exception was raised
finally:
   code # always executed independent of exceptions
         # typically used to clean up (like closing files)
```

except variations

```
# catch all exceptions
except:
                        # only catch exceptions of class ExceptionType
except ExceptionType:
                         # or subclasses of ExceptionType
except (ExceptionType<sub>1</sub>, ExceptionType<sub>2</sub>, ..., ExceptionType<sub>k</sub>):
                         # catch any of k classes (and subclasses)
except ExceptionType as e:
                         # catch exception and assign exception object to e
                         # e.args contains arguments to the raised exception
```

Raising exceptions

• An exception is raised (or trown) using one of the following (the first being an alias for the second):

```
raise ExceptionType
raise ExceptionType()
raise ExceptionType(args)
```

abstract.py class A(): def f(self): print('f') self.g() def g(self): raise NotImplementedError class B(A): def g(self): print('g')

Python shell

```
> B().f()
| f
| g
> A().f()
| f
| NotImplementedError
```

User exceptions

 New exception types are created using class inheritance from an existing exception type (possibly defining __init__)

```
tree-search.py
class SolutionFound(Exception): # new exception
   pass
def recursive tree search(x, tree):
    if isinstance(tree, tuple):
        for child in tree:
            recursive tree search (x, child)
    elif x == tree:
        raise SolutionFound # found x in tree
def tree search(x, tree):
    try:
        recursive tree search(x, tree)
    except SolutionFound:
       print('found', x)
    else:
        print('search for', x, 'unsuccessful')
Python shell
> tree search(8, ((3,2),5,(7,(4,6))))
  search for 8 unsuccessful
> tree search(7, ((3,2),5,(7,(4,6))))
  found 7
```

match - case (since Python 3.10)

- Assume we want to do different things depending on the value of an expression (different cases)
- Can be done using if, but also using match case, that is also evaluated top-down

```
match-case.py
x = 7
if x == 1:
   print('x is one')
elif x == 2:
   print('x is two')
elif x == 3 or x == 4 or x == 5:
   print('x is three, four or five')
else:
    print(x, 'is not in the range 1-5')
Python shell
 7 is not in the range 1-5
```

```
match-case.py
x = 7
match x: # match expression
    case 1:
        print('x is one')
    case 2:
        print('x is two')
    case 3 | 4 | 5: # match any of the cases
        print('x is three, four or five')
    case value: # else, value = variable name
        print(value, 'is not in the range 1-5')
Python shell
  7 is not in the range 1-5
```

match-case

Can match...

- simple values
- named variable values
- guards (if)
- sequences of values
- dictionaries
- builtin types
- user defined classes
- nested structures of the above

```
match-case.py

class Color:
    RED = 'ff0000'
    GREEN = '00ff00'
    BLUE = '0000ff'

class Point:
    __match_args__ = ('x', 'y')
    def __init__(self, x, y):
        self.x = x
        self.y = y

    def __repr__(self):
        return f'Point({self.x}, {self.y})'
```

```
match-case.py
def f(x):
 match x:
    case 42:
        return 'the integer 42'
    case 1 | 2 | 3 | 4 | 5:
        return 'integer in range(1, 6)'
    case (1, 2):
        return 'sequence containing the elements 1 and 2'
    case [x, 2]:
        return 'sequence of length 2, last=2, first=' + str(x)
    case (x, y) if x + y == 7: # quard
        return 'sequence with two values with sum 7'
    case [0, 1, *x]: # x is list of remaining elements in sequence
        return 'sequence starting with 1 and 2, and tail ' + str(x)
    case {'a': 7, 'b': x}:
        return 'dictionary "a" -> 7, "b" -> ' + str(x)
    case (('a' | 'b'), ('c' | 'd')):
        return 'tuple length 2, first "a" or "b", last "c" or "d"'
    case (('x' | 'y') as fst, ('x' | 'y') as snd):
        return '(fst, snd), where fst=' + str(fst) + ', snd=' + str(snd)
    case float(value): # test on builtin type
        return 'a float ' + str(value)
    case Color.RED: # class or object attribute
        return 'the color red'
    case Point(x=7, y=value): # Point object with attributes x and y
        return 'a Point object with x=7, and y=' + str(value)
    case Point(x, y): # requires match args in class Point
        return 'a point Point(' + str(x) + ', ' + str(y) + ')'
    case e: # /! using the wildcard would not bind to a variable
        return 'cannot match ' + repr(e)
```

```
Python shell (match-case.py continued)
```

```
> for x in [42, 1, [1, 2], [7, 2], range(3, 5), (3, (5, 7)), (0, 1, 2, 3, 4, 5), {'a':7, 'b':42, 'c':1},
            ('b', 'c'), ('y', 'x'), 3.14, 'ff0000', Point(7, 42), Point(3, 5), 'abc']:
      print('f(' + repr(x) + ') = ' + repr(f(x)))
  f(42) = 'the integer 42'
  f(1) = 'integer in range(1, 6)'
  f([1, 2]) = 'sequence containing the elements 1 and 2'
  f([7, 2]) = 'sequence of length 2, last=2, first=7'
  f(range(3, 5)) = 'sequence with two values with sum 7'
  f((3, (5, 7))) = 'a triplet (3, (5, 7))'
  f((0, 1, 2, 3, 4, 5)) = 'sequence starting with 1 and 2, and tail [2, 3, 4, 5]'
  f(\{'a': 7, 'b': 42, 'c': 1\}) = 'dictionary "a" -> 7, "b" -> 42'
  f(('b', 'c')) = 'tuple length 2, first "a" or "b", last "c" or "d"'
  f(('y', 'x')) = '(fst, snd), where fst=y, snd=x'
  f(3.14) = 'a float 3.14'
  f('ff0000') = 'the color red'
  f(Point(7, 42)) = 'a Point object with x=7, and y=42'
  f(Point(3, 5)) = 'a point Point(3, 5)'
  f('abc') = "cannot match 'abc'"
```

3 ways to read lines from a file

Steps

- Open file using open
- 2. Read lines from file using
 - a) filehandler.readline
 - b) filehandler.readlines
 - c) for line in filehandler:
- 3. Close file using close

```
open ('filename.txt') assumes the file to be in the same
folder as your Python program, but you can also provide a full path
open('c:/Users/gerth/Documents/filename.txt')
```

```
try to open file
                                         filename
                         for reading
        filehandle
                     reading-file1.py
                     f = open('reading-file1.py')
      iterate over
                     for line in f:
       lines in file
                         print('> ', line, end='')
        close file
                     f.close()
      when done
                     reading-file2.py
     read all lines
                     f = open('reading-file2.py')
      into a list of \longrightarrow
                    lines = f.readlines()
          strings
                     f.close()
                     for line in lines:
                     print('> ', line, end='')
                     reading-file3.py
                     f = open('reading-file3.py')
   read single line
(terminated by '\n')
                     line = f.readline()
                     while line != '':
                         print('> ', line, end='')
                          line = f.readline()
```

f.close()

3 ways to write lines to a file

write single string to file .

write list of strings to file

Opening file:

```
open (filename, mode)
where mode is a string, either 'w' for
opening a new (or truncating an existing file)
and 'a' for appending to an existing file
```

Write single string:

```
filehandle.write(string)
Returns the number of characters written
```

Write list of strings strings:

```
filehandle.writeline(list)
```

- Newlines ('\n') must be written explicitly
- print can take an optional file argument

```
try to open file
                            write mode
   for writing
write-file.py
f = open('output-file.txt', 'w')
f.write('Text 1\n')
f.writelines(['Text 2\n', 'Text 3 '])
f.close()
                            append to existing file
g = open('output-file.txt', 'a')
print('Text 4', file=g)
g.writelines(['Text 5 ', 'Text 6'])
g.close()
output-file.txt
Text 1
Text 2
Text 3 Text 4
Text 5 Text 6
```

Exceptions while dealing with files

When dealing with files one should be prepared to handle errors / raised exceptions, e.g. FileNotFoundError

```
try:
    f = open('reading-file4.py')
except FileNotFoundError:
    print('Could not open file')
else:
    try:
        for line in f:
            print('> ', line, end='')
    finally:
        f.close()
```

Opening files using with (recommend way)

- The Python keyword with allows to create a context manager for handling files
- Filehandle will automatically be closed, also when exceptions occur
- Under the hood: filehandles returned by open support __enter__ and _exit__ methods

Does a file exist?

Module os.path contains a method isfile to check if a file exists

```
checking-files.py
import os.path
filename = input('Filename: ')
if os.path.isfile(filename):
    print('file exists')
else:
    print('file does not exist')
```

module sys

Module sys contains the three standard file handles

```
sys.stdin (used by the input function)
sys.stdout (used by the print function)
sys.stderr (error output from the Python interpreter)
```

print(..., file=output file)

```
sys-print-file.py
import sys
def complicated function(file):
   print('Hello world', file=file) # print to file or STDOUT
while True:
    file name = input('Output file (empty for STDOUT): ')
    if file name == '':
        file = sys.stdout
       break
    else:
        try:
            file = open(file name, 'w')
            break
        except Exception:
            pass
complicated function(file)
if file != sys.stdout:
    file.close()
```

PEP8 on exceptions

- For all try/except clauses, limit the try clause to the absolute minimum amount of code necessary
- The class naming convention applies (CapWords)
- Use the suffix "Error" on your exception names (if the exception actually is an error)
- A bare except: clause will catch SystemExit and KeyboardInterrupt exceptions, making it harder to interrupt a program with Control-C, and can disguise other problems. If you want to catch all exceptions that signal program errors, use except Exception:

Performance of scanning a file

 Python can efficiently scan through quite big files

File	Size	Time
Atom chem shift.csv	≈ 750 MB	≈ 8 sec
<u>cano.txt</u>	≈ 3.7 MB	≈ 0.1 sec

The first search finds all lines related to ThrB12-DKP-insulin (Entry ID 6203) in a chemical database available from www.bmrb.wisc.edu

The second search finds all occurrences of "Germany" in Conan Doyle's complete Sherlock Holmes available at sherlock-holm.es

```
file-scanning.py
from time import time
for filename, query in [
        ('Atom chem shift.csv', ',6203,'),
        ('cano.txt', 'Germany')
    1:
    count = 0
   matches = []
    start = time()
    with open(filename) as f:
        for i, line in enumerate(f, start=1):
            count += 1
            if query in line:
                matches.append((i, line))
    end = time()
    for i, line in matches:
        print(i, ':', line, end='')
    print('Duration:', end - start)
    print(len(matches), 'of', count, 'lines match')
```

Python shell

```
sudoku.py
class Sudoku:
 def init (self, puzzle):
    self.puzzle = puzzle
  def solve(self):
    def find free():
      for i in range(9):
        for j in range(9):
          if self.puzzle[i][j] == 0:
            return (i, j)
      return None
    def unused(i, j):
      i, j = i // 3 * 3, j // 3 * 3
      cells = \{(i, k) \text{ for } k \text{ in range}(9)\}
      cells = \{(k, j) \text{ for } k \text{ in range}(9)\}
      cells = \{(i, j) \text{ for } i \text{ in range}(i, i + 3)\}
